

Backend Developer

Team: OMS & Other Support Systems

Tech Stacks/Tools:

- Java Spring boot
- Apache Kafka
- SAP API's
- SOAP API's
- Dbeaver
- IntelliJ

Tasks of Backend developer:

Once a User Story is generated, the Leads assign each developer what implementation is to be done. The developer then divides these given assignments into chunks and create Tasks in devops. If any confusion arises, there is a discussion with leads to clarify the requirements.

Once the task is created, the developer starts developing API according to the requirement. Once the API development is completed, he works with Unit Test cases.

Finally, when implementation is completed, the build is deployed and given for dev testing. If any issue arises during the testing, then issues are raised and assigned to the respective developer by the lead, after which they start working on fixing the issues.

Once everything is working fine, the build is deployed to replica environment (Similar to production environment) and tested for 48 hours. Once you get a signoff in replica the build is pushed to production (Live).

Uses of Tech Stack:

1. Java Spring boot:
New requirements are written in Java 18. Java 11 is used for older implementation.
2. Database:
 - a. New Data are stored in the below databases:
 - i. Oracle DB
 - ii. My SQL
 - b. MS SQL Server: Contains Older Data
3. Apache Kafka: Used for Logging. All the logs created by publisher are sent and received by all the consumers
4. SAP & SOAP API's:
Although all the new implementations are REST API, there are several legacy API's which uses SOAP/SAP Api's.
5. Dbeaver & IntelliJ:
IntelliJ is an IDE where java code is written whereas Dbeaver is an application which allows developer to access all the database (Since the developer works with different databases.)

Personal Projects:

1. URL-shortener API using Redis, Docker:
Tech Stack: Go-lang, Gin (Golang Framework), Redis, Docker

2. Video-Ad Player:

Tech Stack: Go-lang, ReactJS, HTML, CSS, Docker
